## Triangles

- Similar and Congruent Figures
- Two geometric figures having the same shape and size are said to be congruent figures.
- Two geometric figures having the same shape, but not necessarily the same size, are called similar figures.

## Example:

(1) All circles are similar.
(2) All equilateral triangles are similar.
(3) All congruent figures are similar. However, the converse is not true.

- Similarity of Polygons

Two polygons with the same number of sides are similar, if

- their corresponding angles are equal
- their corresponding sides are in the same ratio (or proportion)
- Two lines segments are congruent, if they are equal in length.
- Two angles are congruent, if they have the same measure.
- СРСТ:

CPCT stands for Corresponding Parts of Congruent Triangles.
If $\triangle \mathrm{ABC} \cong \triangle \mathrm{PQR}$, then corresponding sides are equal i.e., $\mathrm{AB}=\mathrm{PQ}, \mathrm{BC}=\mathrm{QR}$, and $\mathrm{CA}=\mathrm{RP}$ and corresponding angles are equal i.e., $\angle \mathrm{A}=\angle \mathrm{P}, \angle \mathrm{B}=\angle \mathrm{Q}$, and $\angle \mathrm{C}$ $=\angle R$.

## - Basic proportionality theorem:

If a line is drawn parallel to one side of a triangle to intersect the other two sides in distinct points, then the other two sides are divided in the same ratio.

Corollary: If D and E are points on the sides, AB and AC , respectively of $\triangle A B C$ such that $D E \| B C$, then
$\frac{\mathrm{AB}}{\mathrm{AD}}=\frac{\mathrm{AC}}{\mathrm{AE}}$
$\frac{\mathrm{AB}}{\mathrm{DB}}=\frac{\mathrm{AC}}{\mathrm{EC}}$
Example:
In the given figure, S and T are points on PQ and PR respectively of $\triangle \mathrm{PQR}$ such that ST \| QR.

Determine the length of PR.

## Solution:

Since ST \| QR, by basic proportionality theorem, we have
$\frac{\mathbf{P S}}{\mathbf{S Q}}=\frac{\mathbf{P T}}{\mathbf{T R}}$
$\Rightarrow \frac{12}{18}=\frac{3}{\mathrm{TR}}$
$\Rightarrow \mathrm{TR}=\frac{3 \times 1.8}{1.2}=4.5 \mathrm{~cm}$
$\therefore$ PR $=\mathbf{P T}+\mathbf{T R}=(3+45) \mathrm{cm}=75 \mathrm{~cm}$

- Converse of basic proportionality theorem:

If a line divides any two sides of a triangle in the same ratio, then the line is parallel to the third side.

- Theorem: (AAA similarity criterion)

If in two triangles, corresponding angles are equal, then their corresponding sides are in the same ratio (or proportion) and hence, the two triangles are similar.

- Theorem: (AA similarity criterion)

If in two triangles, two angles of one triangle are respectively equal to the two angles of the other triangle, then the two triangles are similar.

## Example:

In $\triangle \mathrm{ABC}, \angle \mathrm{C}$ is acute, D and E are points on sides BC and AC respectively, such that $A D \perp B C$ and $B E \perp A C$. Show that $B C \times C D=A C \times C E$.

## Solution:

In $\triangle \mathrm{ADC}$ and $\triangle \mathrm{BEC}$, $\angle \mathrm{ADC}=\angle \mathrm{BEC}=90^{\circ}$
$\angle \mathrm{DCA}=\angle \mathrm{ECB}$
[Common]
$\therefore$ By AA similarity criterion, $\triangle \mathrm{ADC} \sim \triangle \mathrm{BEC}$
$\therefore \frac{\mathrm{CD}}{\mathrm{CE}}=\frac{\mathrm{AC}}{\mathrm{BC}}$
$\Rightarrow \mathbf{B C} \times \mathbf{C D}=\mathbf{A C} \times \mathbf{C E}$
Hence, the result is proved.

- Theorem: (SSS similarity criterion)

If in two triangles, sides of one triangle are proportional to the sides of the other triangle then the two triangles are similar by SSS similarity criterion.

## Example:

If PQR is an isosceles triangle with $\mathrm{PQ}=\mathrm{PR}$ and A is the mid-point of side QR then prove that $\triangle \mathrm{PAQ}$ is similar to $\triangle \mathrm{PAR}$.

## Solution:

It is given that $\triangle P Q R$ is an isosceles triangle and $P Q=P R$.

In triangles PAQ and PAR, $P Q=P R$
Also, A is the mid-point of QR , therefore $\mathrm{QA}=\mathrm{AR}$
And, PA = PA (Common to both triangles)
Therefore, we can say that

$$
\frac{\mathrm{PQ}}{\mathrm{PR}}=\frac{\mathrm{QA}}{\mathrm{AR}}=\frac{\mathrm{PA}}{\mathrm{PA}}
$$

$\therefore$ Using SSS similarity criterion, we obtain $\triangle \mathrm{PAQ} \sim \triangle \mathrm{PAR}$

- Theorem: (SAS similarity criterion)

If one angle of a triangle is equal to one angle of the other triangle and the sides including these angles are proportional, then the two triangles are similar by SAS similarity criterion.

## Example:

If PQRS is a parallelogram, then prove that $\Delta \mathrm{SOR}$ is similar to $\triangle \mathrm{POQ}$.

## Solution:

Consider $\triangle \mathrm{SOR}$ and $\triangle \mathrm{POQ}$.

Since PQRS is a parallelogram, the diagonals bisect each other.
$\therefore \mathrm{SO}=\mathrm{OQ}$ and $\mathrm{PO}=\mathrm{OR}$
and $\angle \mathrm{POQ}=\angle \mathrm{SOR}$ (Vertically opposite angles)
By SAS similarity criterion, we obtain
$\Delta$ SOR ~ $\Delta$ QOP

- Areas of similar triangles

Theorem: The ratio of the areas of two similar triangles is equal to the square of the ratio of their corresponding sides.

## Example:

In $\triangle A B C, D$ and $E$ are the respective mid-points of sides $A B$ and $B C$. Find the ratio of the areas of $\triangle \mathrm{DBE}$ and $\triangle \mathrm{ABC}$.

## Solution:

In $\triangle A B C, D$ and $E$ are the respective mid-points of the sides, $A B$ and $B C$.
By the converse of BPT, DE\|AC
In $\triangle \mathrm{DBE}$ and $\triangle \mathrm{ABC}$,
$\angle \mathrm{DBE}=\angle \mathrm{ABC} \quad$ [Common]
$\angle \mathrm{BED}=\angle \mathrm{BCA} \quad$ [Corresponding angles]
$\angle \mathrm{BDE}=\angle \mathrm{BAC} \quad$ [Corresponding angles]
$\therefore$ By AAA similarity criterion, $\triangle \mathrm{DBE} \sim \triangle \mathrm{ABC}$
$\Rightarrow \frac{\text { Area }(\triangle \mathrm{DBE})}{\text { Area }(\triangle \mathrm{ABC})}=\left(\frac{\mathrm{BE}}{\mathrm{BC}}\right)^{2}$
$=\left(\frac{\mathbf{B E}}{2 B E}\right)^{2} \quad[\mathrm{E}$ is mid point of BC$]$
$=\frac{1}{4}$
$=1: 4$
Result: Using the above theorem, the result " the ratio of the areas of two similar triangles is equal to the square of the ratio of their corresponding medians or altitudes or angle bisector" can be proved.

- Pythagoras theorem:

In a right triangle, the square of the hypotenuse is equal to the sum of the squares of the other two sides.

## Example:

$\triangle \mathrm{ABC}$ is right-angled at B and $\mathrm{BD} \perp \mathrm{CA}$.

Prove that $\mathrm{BD}^{2}=\mathrm{CD} \times \mathrm{DA}$.
Solution:
By applying Pythagoras theorem in $\triangle \mathrm{BDC}, \triangle \mathrm{BDA}$, and $\triangle \mathrm{ABC}$, we obtain

$$
\begin{equation*}
\mathrm{BC}^{2}=\mathrm{CD}^{2}+\mathrm{BD}^{2} \tag{1}
\end{equation*}
$$

$\mathrm{BA}^{2}=\mathrm{BD}^{2}+\mathrm{DA}^{2}$
$\mathrm{CA}^{2}=\mathrm{BC}^{2}+\mathrm{BA}^{2}$
Adding equations (1) and (2), we obtain
$\mathrm{BC}^{2}+\mathrm{BA}^{2}=2 \mathrm{BD}^{2}+\mathrm{CD}^{2}+\mathrm{DA}^{2}$
$\Rightarrow \mathrm{CA}^{2}=2 \mathrm{BD}^{2}+\mathrm{CD}^{2}+\mathrm{DA}^{2} \quad \ldots[$ Using (3)]
$\Rightarrow(C D+D A)^{2}=2 \mathrm{BD}^{2}+\mathrm{CD}^{2}+\mathrm{DA}^{2}$
$\Rightarrow \mathrm{CD}^{2}+\mathrm{DA}^{2}+2 \times \mathrm{CD} \times \mathrm{DA}=2 \mathrm{BD}^{2}+\mathrm{CD}^{2}+\mathrm{DA}^{2}$
$\Rightarrow \mathrm{CD} \times \mathrm{DA}=\mathrm{BD}^{2}$

## - Converse of Pythagoras theorem:

In a triangle, if the square of one side is equal to the sum of the squares of other two sides, then the angle opposite to the first side is a right angle.
